Tackling Situated Multi-Modal Task-Oriented Dialogs with a Single Transformer Model

Anonymous ACL submission

Abstract

The Situated Interactive Multi-Modal Conversations (SIMMC) 2.0 aims to create virtual shopping assistants that can accept complex multi-modal inputs, i.e. visual appearances of objects and user utterances. It consists of four subtasks, multi-modal disambiguation (MM-Disamb), multi-modal coreference resolution (MM-Coref), multi-modal dialog state tracking (MM-DST), and response retrieval and generation. While many task-oriented dialog systems usually tackle each subtask separately, we propose a jointly learned encoder-decoder that performs all four subtasks at once for efficiency. Moreover, we handle the multi-modality of the challenge by representing visual objects as special tokens whose joint embedding is learned via auxiliary tasks. This approach won the MM-Coref and response retrieval subtasks and nominated runner-up for the remaining subtasks using a single unified model. In particular, our model achieved 81.5% MRR, 71.2% R@1, 95.0% R@5, 98.2% R@10, and 1.9 mean rank in response retrieval task, setting a high bar for the state-of-the-art result in the SIMMC 2.0 track of the Dialog Systems Technology Challenge 10 (DSTC10).

1 Introduction

A task-oriented dialog system aims to assist users accomplish certain tasks, such as executing actions or retrieving specific information, with natural language conversations. The traditional approach for building task-oriented dialog systems adopts a pipelined architecture that integrates natural language understanding (NLU) module that identifies user's intent (Liu and Lane, 2016), dialog state tracking (DST) module that extracts values for slots (Henderson et al., 2013; Mrksic et al., 2017), dialog policy management (POL) module that decides system action (Wen et al., 2017), and natural language generation (NLG) module that generates appropriate system utterance according to system action (Wen et al., 2015).

With the rising interest and ubiquity of virtual reality (VR), the next generation of task-oriented virtual assistants is expected to handle conversations in a multi-modal context. For instance, a multi-modal dialog agent may help the user navigate a virtual clothing store and look for an object meeting the user's criteria. In such cases, a successful dialog agent should be able to parse and understand multi-modal contexts. To this end, SIMMC 2.0 (Kottur et al., 2021) proposes a situated multi-modal context in the form of co-observed, realistic scene set in VR stores to incorporate the complexity of multi-modal task-oriented dialogs. The multi-modal subtasks, MM-Disamb and MM-Coref, intend to test the assistant's capability to identify the need for disambiguating reference mentions and to ground them to the scene objects. While challenging, these are all essential to building a successful multi-modal dialog agent.

In this paper, we present our end-to-end, joint-learning approach to address this challenge in SIMMC 2.0. We adopt BART (Lewis et al., 2019) and attach task-specific heads so that the model can make predictions on all subtasks. To be more specific, our model performs MM-Disamb, MM-Coref, and response retrieval by the encoder and MM-DST and response generation in a string format by the decoder. We also integrate multi-modality into the model by treating scene objects as unique object tokens and coreference sentinel tokens. Our model is jointly trained on all subtasks and a few auxiliary objectives to help the model align object tokens to its attributes. For retrieval, we use in-batch negative samples for contrastive metric learning instead of creating a pool of separate training samples.

Our model was ranked at the first place for MM-Coref and response retrieval with 75.8% coreference F1, 81.5% MRR, 71.2% R@1, 95.0% R@5, 98.2% R@10, and 1.9 mean rank in the official evaluation of DSTC10. Moreover, our model was nominated runner-up for all other subtasks, in which we

achieved 93.8% disambiguation accuracy, 90.3% slot F1, 95.9% intent F1, and 0.295 BLEU-4. The results were obtained with only a single model and consistent with the results on the devtest (i.e. validation) set, demonstrating a robust, common representation on all subtasks learned by the model.

2 Related Work

Recent works on task-oriented dialog systems remove the need for a pipeline composed of NLU, DST, POL, and NLG modules by leveraging pretrained language models (LM) that integrate all the modules in an end-to-end, auto-regressive manner (Ham et al., 2020; Hosseini-Asl et al., 2020; Yang et al., 2021). Given a dialog context, such systems sequentially generates belief state, system action, and response, making predictions based on decisions made by previous modules in the form of tokens. Some of these systems aim to learn the user preference from dialogs and recommend the object based on external knowledge base (KB) (Zhou et al., 2020).

In a similar context, building cross-modal models has recently gained a lot of attention, especially in the domain of vision and language (VL). Recent works develop VL models on top of the transformer-based (Vaswani et al., 2017) pretrained LM and vision backbones, focusing on pretraining methods to align joint embedding between different modalities. They achieve state-of-the-art performance in downstream tasks such as visual question answering (VQA), as shown in (Chen et al., 2020) and (Li et al., 2020). In this paper, we focus on understanding objects (i.e. shopping items) appearing in a scene, observed by both user and assistant. Based on the objects in a scene, the assistant needs to recommend objects or provide information of objects in the response.

3 SIMMC 2.0 Description

3.1 Dataset

SIMMC 2.0 (Kottur et al., 2021) follows the setting of SIMMC 1.0 (Moon et al., 2020), which assumed conversations occurring between a user and an assistant in a situated, co-observed VR scene. This newer iteration of the dataset lifts the limitations of SIMMC 1.0 by further capturing the complexity of multi-modal conversations: whereas SIMMC 1.0 had at most three objects in a simple, sanitized scene, SIMMC 2.0 provides a far richer visual context with 19.7 objects on average that are often occluded, cluttered, or even out of view. An example dialog is shown in Figure 1.

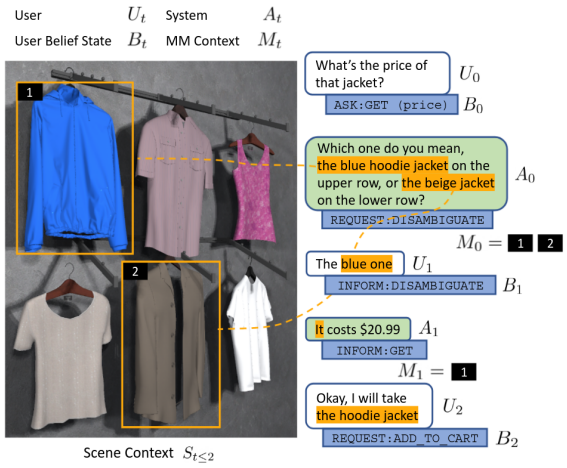

Figure 1: An instance of dialog and the corresponding scene in SIMMC 2.0. Here, the assistant asks the user to disambiguate between *the blue hoodie jacket* (indexed as 1) and *the beige jacket* (indexed as 2), grounding its mentions to the scene via multi-modal context $M_0 = \{1, 2\}$. Once the user chooses *the blue one*, the system retrieves the information on the disambiguated object. The multi-modal context in this case would be $M_1 = \{1\}$.

The SIMMC 2.0 dataset consists of 11,244 dialogs split into train (65%), dev (5%), devtest (15%), and teststd (15%) sets. Each dialog includes multiple turns where each turn has grounded multi-modal context and an accompanying scene with referential indices. We shall denote a SIMMC dialog with r rounds as $\mathcal{D} := \{(U_t, A_t, M_t, S_t, B_t)\}_{t=1}^{r}$, where U_t is user utterance, A_t system utterance, M_t multi-modal context, S_t scene context, and B_t user belief state at turn t. Here, M_t is a set of object indices mentioned by the system and S_t contains the corresponding attributes and locations of all the objects in a scene. User belief state B_t is composed of dialog act (i.e. user intent) and slot (i.e. a tuple of (*slot name*, value), for instance ("price", "$11.99")). We also define the dialog history at some turn $T \leq r$ as $H_T := \{U_0, A_0, M_0, \ldots, U_{T-1}, A_{T-1}, M_{T-1}\}$.

The assistant needs to make predictions conditioned on history H_T, current user utterance U_T, and the scenes up to the current turn $S_{t\leq T}$. The object set consists of fashion and furniture domain, where each domain has 288 and 57 items respectively. The system is allowed to look up which item is present in a scene at all time. As a side information, the metadata of each object are provided: its

non-visual attributes such as brand, size, customer rating and price are available for both training and inference, but looking up the visual attribute (e.g. color, pattern, materials, sleeve length) is prohibited for inference so as to make the agent reason with multi-modal information.

3.2 Subtasks

Multi-modal disambiguation (MM-Disamb) The first subtask is to identify whether the assistant should disambiguate mentions in the next turn given the dialog and multi-modal context. For instance, given user utterance "*How much is the pair on the left?*", there may be more than two pairs of pants on the left. In this case, ambiguity in reference should be resolved. This can be cast into a binary classification task, and the performance is measured by accuracy.

Multi-modal coreference resolution (MM-Coref) The second subtask is to map the referential mentions of the user utterance to the object indices in the scene. These mentions should be resolved through the linguistic context and the multi-modal context. The performance is measured by object slot F1 score.

Multi-modal dialog state tracking (MM-DST) The third subtask extends the traditional uni-modal DST to ground user belief state on the multi-modal objects. This will measure the assistant's understanding throughout each dialog, which includes disambiguation and coreference resolution. The performance is measured by the F1 score for dialog act and slots.

Response retrieval & generation The last subtask is to retrieve or generate appropriate system utterance. Response generation is evaluated with BLEU-4 (Papineni et al., 2002). For response retrieval, the system is expected to choose the most relevant response from a pool of 100 candidate responses. Recall@k ($k \in \{1, 5, 10\}$), mean rank, and mean reciprocal rank (MRR) are used for retrieval evaluation.

4 Integrated Transformer Model

Even though the setting of the dataset is similar to that of VQA where finetuning the pretrained VL models are prevalent, we chose to work with LM, representing objects by tokens. There are several reasons behind this choice. First, the vision models are usually pretrained on natural images (Lin et al., 2014; Krishna et al., 2017), so finetuning them requires a relatively large number of training samples of 3D rendered images that are aligned properly with text. Second, in a realistic scenario where the assistant is deployed in a VR environment, the object metadata and scene graphs would be readily available as a part of the system. In this case, using a vision backbone model would be an unnecessary overhead. Lastly, we can still easily provide additional supervision signals at train time for modality alignment by looking up the object metadata. For this, we represent multi-modal objects as the concatenation of their referential indices in the scene (canonical object ID) and their absolute attribute (unique object ID).

We note that all of the subtasks are related to each other. For example, if the assistant decides that the user utterance needs to be disambiguated, then the appropriate system action is to respond along the line of "*Which one are you referring to?*". We expect that the latent representation of the multi-modal dialog learned from other subtasks will translate readily to other subtasks. Hence, we utilize hard parameter sharing (Caruana, 1993) on the encoder to jointly learn on all subtasks. This reduces not only the number of network parameters, but also the risk of overfitting (Baxter, 1997).

Moreover, we decide to view MM-Coref as a type of set prediction (Zaheer et al., 2017), where joint learning of set cardinality and state distribution has been shown effective (Rezatofighi et al., 2018). Hence, we define an additional empty coreference target prediction (Empty-Coref), a simplified cardinality prediction task that outputs whether the current user utterance has no MM-Coref targets. Moreover, we perform a supervised learning on object attributes to help align object-language modalities.

In order to harness the power of NLU/NLG capabilities demonstrated by pretrained transformer encoder-decoder, we adopt BART (Lewis et al., 2019) as the pretrained language backbone. We attach classification heads for MM-Disamb and MM-Coref subtasks at the encoder and LM head for MM-DST and response generation at the decoder. We also perform retrieval by computing the dot product between representation vectors of response candidates and multi-modal dialog context. The overview of the model is provided in Figure 2.

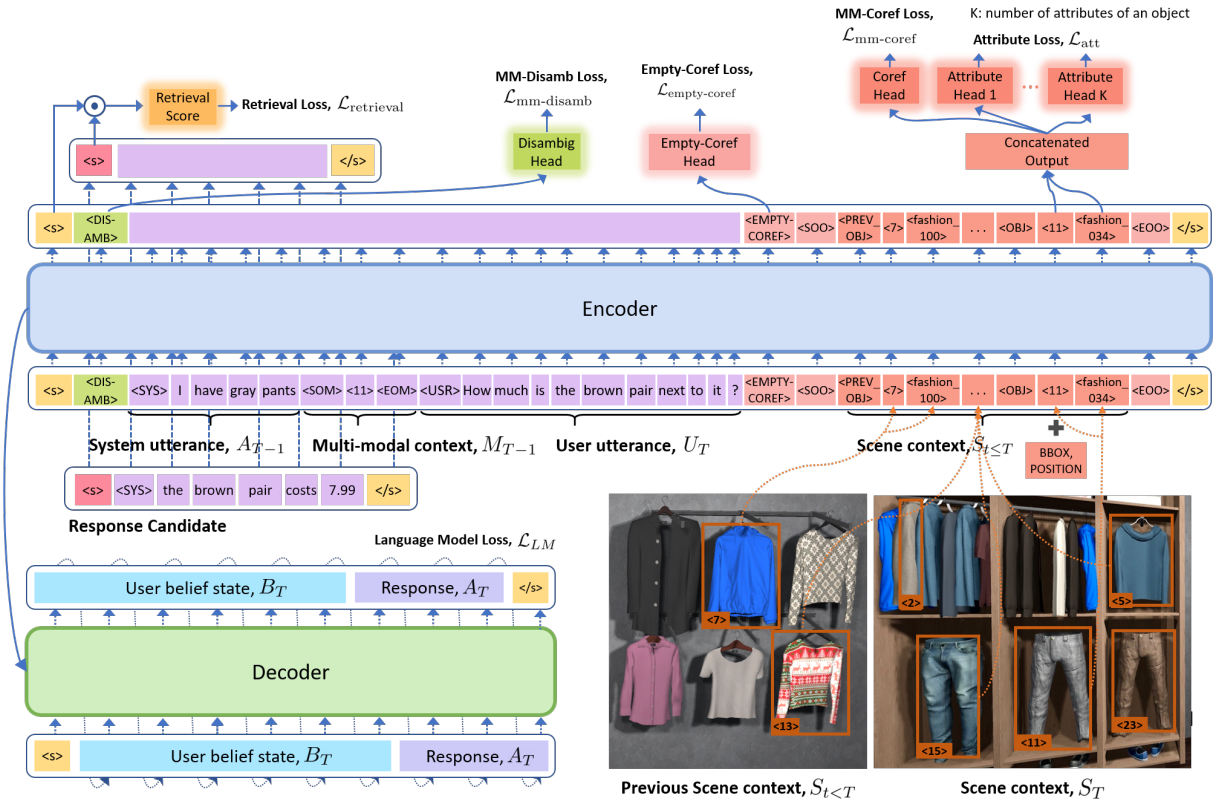

Figure 2: Overview of the jointly learned multi-tasking BART. For H_T, we show only the last turn without user utterance due to space limit. The details on the loss functions are provided in model specifics. Each scene object is represented by the concatenation of scene canonical object ID token (e.g. <11>) and unique object token (e.g. <fashion_123>). It is then passed through MM-Coref and attribute classification head. MM-DST and response generation subtasks are approached in terms of auto-regressive LM.

4.1 Input Representation

For all of the subtasks, we define our input to be a simple concatenation $x := [H_T; U_T; S_{t\leq T}]$ with separators. We define H_T to be the dialog history up to 2 turns to limit the length of input, i.e. $\{U_{T-2}, A_{T-2}, M_{T-2}, U_{T-1}, A_{T-1}, M_{T-1}\}$. SIMMC 2.0 assumes that utterances may mention objects that are not in the current scene S_T but in the previously observed scene $S_{t<T} \neq S_T$. Hence, our model integrates the objects from the previous scene that are not in the current scene. We find that our scene representation by enumerating all objects is a simple yet effective method for the model to understand the multi-modal context. An examplar input is provided in Table 1.

4.1.1 Canonical object ID token

A canonical object ID token takes the form of <\d+> (e.g. <32>). This provides a relational context of the object within the scene, grounding each object to its scene object index provided in the dataset. This scheme was also used in the baseline code for SIMMC 2.0 (Kottur et al., 2021), but without any association to object attributes. In our method, this token intends to provide contextual information of the object alongside its absolute attributes (unique object token), allowing the assistant to make connections between different modalities.

4.1.2 Unique object ID token

Unique object ID token takes the form of <{domain}_\d+> (e.g. <fashion_123>, <furniture_028>). The digits following the domain specifier denote index of the unique object in that domain. This token intends to provide an embedding which encodes the visual (e.g. type, color, material) and non-visual (e.g. price, customer rating) attributes unique to each object.

4.1.3 Separator tokens

We define several separator tokens to delimit different components of the multi-modal dialogs. We use <SOM>, <EOM> for the start and the end of multi-modal context and <SOO>, <EOO> for the

Common Input (x)	
U_{T-1}	<USR> What are the good hoodies around here?
A_{T-1}	<SYS> I advise you consider the solid green one.
M_{T-1}	<SOM> <56> <EOM>
U_T	<USR> I do like solid colors, but I'm looking for something with excellent ratings.
$S_{t<T}$	<SOO> <PREV_OBJ> <12> <fashion_142> <PREV_OBJ> <13> <fashion_058>
S_T	<OBJ> <56> <fashion_269> <OBJ> <85> <fashion_007> <EOO>
Generation Target	
B_T	<SOB> INFORM:GET <customerReview> good <pattern> plain <type> hoodie <EOB>
A_T	In fact, that green hoodie is very highly rated.
Response Candidate	<SYS> In fact, that green hoodie is very highly rated.

Table 1: Example input representations for our model. We show only up to last 1 turn due to space limit. Thus, the common input x is a concatenation $[H_T; U_T; S_{t\leq T}]$ where $H_T = \{U_{T-1}, A_{T-1}, M_{T-1}\}$. Here, we separate the previous scene history $S_{t<T}$ to show how we handle out-of-view objects. The generation target is a concatenation $[B_T; A_T]$, which is used by the decoder. The response candidate is A_T with speaker identifier <SYS> prepended.

start and the end of scene objects. Within the scene context, <OBJ> token is used as a separator token between objects, which are represented by the concatenation of a canonical object ID token and a unique object ID token. We also mark the objects from the previous scene with <PREV_OBJ> instead of <OBJ>. For generation target, we mark the start and the end of the user belief state with <SOB>, <EOB>.

4.1.4 Encoding object locations

For the assistant to understand the spatial relation among objects within the scene, we must incorporate encoded representation of location of each object. We follow the commonly used techniques in VL models (Li et al., 2020; Chen et al., 2020; Zhang et al., 2021) for encoding object locations with the bounding box information. Given a bounding box represented by its upper-left and lower-right vertices, (x_1, y_1) and (x_2, y_2), with height h and width w, we encode its location as tuple $(x_1/w - 0.5, y_1/h - 0.5, x_2/w - 0.5, y_2/h - 0.5, (x_2 - x_1)(y_2 - y_1)/(h \cdot w))$. This is passed through a location embedding layer (a fully-connected layer followed by layer norm) to be added with the canonical object ID token encoding.

4.2 Model Specifics

4.2.1 Binary prediction for MM-Disamb and MM-Coref

We formulate MM-Disamb as a binary classification on the pooled output of the encoder from the pooling token <DISAMB>. The binary head for MM-Disamb should predict true if the current user utterance U_T needs to be disambiguated and false otherwise.

For MM-Coref, we make binary predictions on all objects in $S_{t\leq T}$. We do so by passing the concatenated canonical object (e.g. <11>) and unique object ID (e.g. <fashion_001>) encoder output of each object through a binary classification head. The MM-Coref head will predict true if the current user utterance mentions that object and false otherwise. We use a simple cross-entropy loss for both MM-Disamb and MM-Coref, denoted $\mathcal{L}_{\text{mm-disamb}}$ and $\mathcal{L}_{\text{mm-coref}}$.

4.2.2 Auto-regressive LM for MM-DST and generation

We also approach MM-DST and response generation subtasks with auto-regressive LM following the recent approaches in end-to-end dialog systems. For MM-DST and response generation, we use the standard left-to-right LM loss (Bengio et al., 2003).

$$\mathcal{L}_{\text{LM}} = \sum_{i=1}^{L} -\log P(\omega_i \mid \omega_1, \ldots, \omega_{i-1}),$$

where ω_i is the i-th target token and L the total length of the target.

4.2.3 In-batch negative samples for retrieval

For response retrieval task, we make use of in-batch negative samples for contrastive learning on similarity metrics. We treat the system responses of the other samples in the batch formatted according to Table 1 as in-batch negatives. We then pool the encoder outputs of the input and the response candidates with BART bos token, i.e. <s>, to compute their dot product, so that the correct scene-response candidate pair stays close and the incorrect pairs stay apart. We use multi-class cross-entropy loss

applied to dot-product similarities, i.e.,

$$\mathcal{L}_{\text{retrieval}} = -\log \frac{\exp(\mathbf{x} \cdot \mathbf{a}^+)}{\sum_{\mathbf{a}^- \in B^-(\mathbf{x}) \cup \{\mathbf{a}^+\}} \exp(\mathbf{x} \cdot \mathbf{a}^-)},$$

where $\mathbf{a}^+$ is the positive response sample of the input $\mathbf{x}$ and $B^-(\mathbf{x})$ the set of in-batch negative responses (assume $\mathbf{x}$, $\mathbf{a}^+$, and $\mathbf{a}^-$ are pooled representations from the encoder). We formulate the task loss $\mathcal{L}_{\text{task}}$ as a linear combination of losses from each subtask.

$$\begin{aligned}\mathcal{L}_{\text{task}} = \; & \lambda_{\text{LM}}\mathcal{L}_{\text{LM}} + \lambda_{\text{mm-disamb}}\mathcal{L}_{\text{mm-disamb}} \\ & + \lambda_{\text{mm-coref}}\mathcal{L}_{\text{mm-coref}} + \lambda_{\text{retrieval}}\mathcal{L}_{\text{retrieval}}\end{aligned} \tag{1}$$

4.3 Auxiliary Tasks

4.3.1 Binary prediction for Empty-Coref

We define an additional Empty-Coref task, in which the assistant predicts whether the current dialog turn has MM-Coref targets. This can be seen as a simpler version of set cardinality prediction. We find this additional signal for coreference resolution, denoted $\mathcal{L}_{\text{empty-coref}}$, is advantageous in boosting MM-Coref performance, a type of set prediction task. Moreover, MM-Coref sometimes predicts targets when there is actually none, so we override any MM-Coref predictions if the Empty-Coref prediction is true (i.e. there is no coreference target). For this, we use `<EMPTY_COREF>` for pooling. At inference time, . We use a binary cross-entropy loss for $\mathcal{L}_{\text{empty-coref}}$.

4.3.2 Encoding object attributes

We encode object attributes by providing additional supervision signal during training. We do so by simply training to classify each object to its corresponding visual and non-visual attributes such as color, price, and customer ratings. Each object is represented as a concatenation of its canonical object ID and unique object token as in MM-Coref (refer to Figure 2). Each attribute head predicts a categorical class for each corresponding object, for example, if `<fashion_001>` is a grey jacket, the color-attribute head predicts the class of grey and the type-attribute head predicts the class of jacket.

Let $\mathcal{O}_{t \le T}$ be the set of objects in the scene history, $S_{t \le T}$. We denote attribute multi-class classification loss $\mathcal{L}_{\text{att}}$ for all objects in $\mathcal{O}_{t \le T}$,

$$\mathcal{L}_{\text{att}} = \sum_{j \in \mathcal{O}_{t \le T}} \sum_{k=1}^{K} \sum_{c \in \mathcal{C}_k} -\mathbb{1}\{c = y_{jk}\} \log P(c),$$

where K is the number of attributes, $\mathcal{C}_k$ the set of all classes of the k-th attribute, y_{jk} the label of the k-th attribute of the j-th object, and $\mathbb{1}\{\cdot\}$ is an indicator function.

As a result, the auxiliary loss $\mathcal{L}_{\text{aux}}$ is defined as the weighted sum of attribute loss and empty-coreference prediction loss:

$$\mathcal{L}_{\text{aux}} = \lambda_{\text{att}}\mathcal{L}_{\text{att}} + \lambda_{\text{empty-coref}}\mathcal{L}_{\text{empty-coref}} \tag{2}$$

In summary, we minimize the total loss $\mathcal{L}_{\text{total}}$, which is the sum of the task loss $\mathcal{L}_{\text{task}}$ from Equation 1 and the auxiliary loss $\mathcal{L}_{\text{aux}}$ from Equation 2.

$$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{task}} + \mathcal{L}_{\text{aux}}$$

5 Experiments

5.1 Experimental Setup

Our model is built on top of 24-layer BART from HuggingFace (`facebook/bart-large`) (Wolf et al., 2019).[1] We finetune the model for 10 epochs with an initial learning rate of 5e-5 and a batch size of 16 with AdamW optimizer (Loshchilov and Hutter, 2018). We also use linear warmup schedule with 8000 warmup steps and clip gradient norms at 1.0. For decoding, we use top-p sampling (Holtzman et al., 2020) with $p = 0.9$ to generate the user belief state and system response. We choose the best checkpoint evaluated at every 1000 steps on the devtest set. For joint learning coefficients, see Appendix A.

5.2 Baselines

The challenge organizers provided two baseline models: an end-to-end GPT-2 (Radford et al., 2019) and multi-modal transformer networks (MTN) (Le et al., 2019). The baseline models do not explicitly use object attributes and model each subtask separately, except for MM-Coref, MM-DST, and response generation. GPT-2 baseline generates the user belief state, coreference objects (in the form of canonical object IDs), and response in an end-to-end manner. MTN baseline conditions on the scene image and dialog history then generate the user belief state and response using a multi-model transformer. The MTN baseline only implements MM-DST and response generation.

5.3 Results

The results on the devtest (validation) and teststd (test) splits are shown in Table 2 and 3, respectively. On devtest set, our proposed model outperforms the baselines by a large margin. Our proposed model based on bart−large was ranked at the first place with 75.8% coreference F1 in MM-Coref. This demonstrates that our method of injecting object attributes to the model was effective, providing a richer context about the scene and its objects to the assistant. Furthermore, our model was declared winner in the response retrieval subtask with 71.2% R@1, 95.0% R@5, 98.2% R@10, and 1.9 mean rank. This is a remarkable performance compared to existing methods such as bi- and poly-encoders (Humeau et al., 2020), despite the fact that we only used a single encoder built into the model to encode both the dialog context and candidates.

Our method of representing scene and learning joint embedding between dialog and scene successfully captured fine-grained information on the scene objects. This allows for the model to attend and focus on objects that are being mentioned in the conversation, learning to choose the right response most of the time. Moreover, our model showed competitive performance and was declared runner-up in all remaining sub-tasks, in which we achieved 93.8% disambiguation accuracy, 90.3% slot F1, 95.9% intent F1, and 0.295 BLEU-4 with a single model.

5.4 Ablation Studies

We conducted ablation studies on auxiliary objectives, namely removing (1) attribute classification and (2) Empty-Coref target set prediction during training, to observe their effectiveness in the assistant's understanding of multi-modality and overall performance in the four subtasks. All ablation models are trained in the same setting as in the earlier part of this section. The results are shown in Table2.

5.4.1 Attribute classification

We remove the attribute classification loss $\mathcal{L}_{\text{att}}$ from the main loss. We observe that removing attribute classification results in a significant drop in the MM-Coref performance by 6.0%. The performance degradation demonstrates the effectiveness of the attribute classification objective. Furthermore, we observe noticeable drop in performance in other subtasks, especially the slot prediction of MM-DST subtasks. Here, understanding and dis-

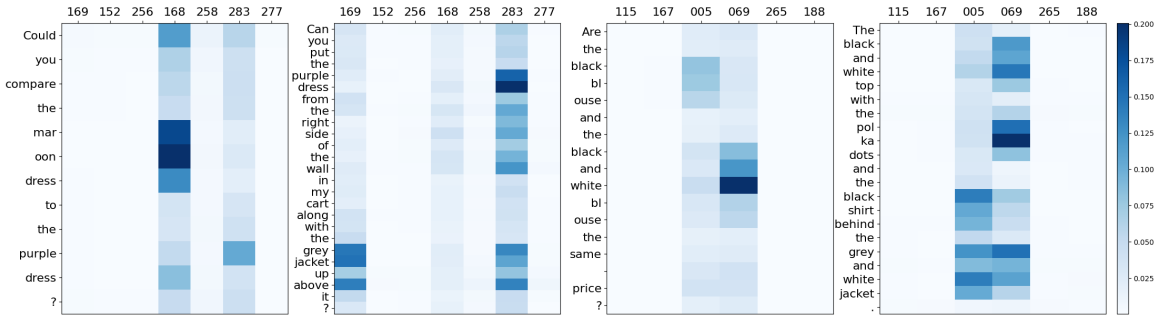

Figure 3: Attention maps between utterance and fashion unique IDs. The object attributes are given in Table 4.

tinguishing different objects by their attributes are crucial in predicting correct slot values.

5.4.2 Empty-Coref prediction

We remove the Empty-Coref loss $\mathcal{L}_{\text{empty-coref}}$ from the main loss. We observe no significant difference from the full model. In fact, we observe a better performance in MM-coref possibly because there is no interference in subtask losses from the Empty-Coref objective. However, Empty-Coref prediction becomes important when the attribute classification objective is removed. The model only achieves 48.7% coreference F1 as opposed to 68.3% with Empty-Coref. This suggests that this auxiliary subtask provides a useful signal for MM-Coref. We also see overall improvements in other related subtasks such as MM-DST and response retrieval.

fashion unique ID	color	type	pattern

265	blue	jeans	denim
188	blue	trousers	plain

Table 4: Visual metadata of unique object IDs shown in Figure 3.

6 Visualizing attention

We visualize the learned attention between the two different modalities. Figure 3 shows attention heatmaps from the fifth head in last encoder layer. The rows indicate extracted utterance from $[H_T; U_T]$ and the columns unique object IDs in in $S_{t \leq T}$. Table 4 lists the visual-metadata of these objects. According to the visualization, the model was able to make a connection between natural language attributes mentioned in the dialog and the corresponding unique object ID token.

7 Conclusion

In this paper, we propose a multi-modal task-oriented dialog system based on BART that can perform all SIMMC 2.0 subtasks at once. Our model overcomes the challenge of adopting severely occluded, 3D rendered artificial images to vision models by integrating multi-modal objects as special tokens. In addition to joint learning of all subtasks, we introduce Empty-Coref and attribute classification as auxiliary tasks to directly align objects to their corresponding attributes. We observe that these additional subtasks are crucial in building a successful multi-modal assistant for SIMMC 2.0. Our model is able to perform competitively in all of the subtasks with a single model, ranking first place for MM-Coref and response retrieval and runner-up for the remaining subtasks in DSTC10.

Despite the success in SIMMC 2.0, our approach has a few limitations. Most notably, our approach cannot be applied to cases with novel objects at inference, i.e. the objects that don't appear in the database at training. As such, it relies on latent object features learned from linguistic description for retrieving the requested object attributes. Our method also does not fully capture the semantic locality of objects within the scene (e.g. on the table, in the closet, etc.). We believe that these limitations can be addressed by training with a larger amount of data and including visual features in the multi-modal context as part of the input to the transformer.

A Implementation Details

A.1 Joint Learning Coefficients

We train the model jointly for all subtasks with two more auxiliary tasks. The total loss is the sum of the subtask loss from Equation 1 and the auxiliary loss from Equation 2. We found the optimal combination of coefficients via grid search with the following choice of coefficient, while fixing $\mathcal{L}_{\text{LM}}$ to 1.0. Table 5 shows the final choice of coefficients used for training.

- $\lambda_{\text{mm-disamb}}, \lambda_{\text{att}}, \lambda_{\text{empty-coref}} \in \{0.1, 0.2, 0.3\}$
- $\lambda_{\text{mm-coref}} \in \{0.8, 1.0\}$
- $\lambda_{\text{retrieval}} \in \{0.2, 0.4, 0.6, 0.8\}$

λ_{LM}	$\lambda_{\text{mm-disamb}}$	$\lambda_{\text{mm-coref}}$
1.0	0.1	0.8
$\lambda_{\text{retrieval}}$	λ_{att}	$\lambda_{\text{empty-coref}}$
0.4	0.1	0.1

Table 5: Optimal choice of joint learning coefficients used for training.

A.2 Task-Specific Heads

Object related classification heads (MM-Coref, attribute classification) have input dimension of twice the model dimension of BART (i.e. 2048 for `bart-large`). For MM-Disamb and Empty-Coref classification head, we use a single linear layer with softmax activation. For MM-Coref and attribute classification, we use an intermediate layer with the same hidden size as the input dimension, which is followed by a linear layer with softmax activation.

U_T	*Can you show me a jacket that goes with my wardrobe?*
Generated A_T	*There are several jackets which match your criteria, including a black jacket, a grey and white jacket, and a light grey jacket.*
GT A_T	*There are a couple of jackets throughout the store that you might like. What do you think?*
U_T	*Can you recommend a jacket to match my clothes?*
Generated A_T	*Do you like the blue one on the bottom row of the wall? It is a jacket.*
GT A_T	*Do you like the brown one on the top left of the wall or the blue one directly under it? They are jackets.*
U_T	*Can you help me find a cheap blouse?*
Generated A_T	*What do you think of the grey and white blouse **on the wall**, the maroon, white, and blue **on the rack**, or the white and grey **on the back wall**?*
GT A_T	*There are three options **on the left wall**: a grey and white, a white and grey, and a maroon, white, and blue?*

U_T	*What is the rating and price of that gray and white shirt?*
Generated A_T	*Which one?*
GT A_T	*Which one?*
U_T	*The gray and white one hanging on the left.*
Generated A_T	*The grey one is $239.99 and the brown one is only $59.99.*
GT A_T	*Sure! The brown one is $59.99 and the grey one is $239.99.*
U_T	*The green and white blouse in the closet and the red, white, and yellow blouse on the rack.*
Generated A_T	*The former is from **Downtown Consignment** and is available in **S, XL, and XXL**. The latter is from **Pedals & Gears** and is in stock in **XS, S and XL**.*
GT A_T	*The first is available in **XS, S, and XL** and is from **The Vegan Baker**. The other is in **XS, S, and XL** and is from **Downtown Consignment**.*

Table 7: Comparison between Generated and GT A_T in the case of disambiguation and informing object attributes. The differences between the generated and the ground-truth (in terms of semantics) are bolded.

B Qualitative analysis

A successful multi-modal agent should be able to recommend objects that fit the user's requested criteria within the scene context, understand the locations of the objects, and provide the requested information on the object such as ratings and price. We qualitatively analyze the generated system utterances to check whether our model can capture the object attributes along with spatial information.

B.1 Recommending objects from scene

Refer to Table 6 for examples. Upon inspecting generated samples, we observe that our model is often able to recommend appropriate objects that fall under the user's criteria. The first example take place in a scene with jackets with the color attributes mentioned by the system Generated A_T, demonstrating the ability to capture object attributes. The second example demonstrates the case where the system correctly recommend and ground jacket to the correct location.

However, it is not hard to find cases where the system is able to recommend the correct objects but in a wrong location. The third example demonstrates such case. All of the three recommended objects match those in the ground-truth response, but the system believes that they are all at a different location when in fact they are all on the left wall. We conjecture that our method of encoding object locations did not provide enough spatial information especially because we do not integrate the store structure itself. The retrieved A_T with

the same dialog yield the correct response since all negative samples in the candidate pool did not contain all of the three objects mentioned in the ground truth.

B.2 Predicting coreference object and attributes

Refer to Table 7 for examples. We see that the model successfully identifies which objects and slots are being queried. In most cases, the model outputs the exact corresponding object information without having to lookup the object metadata directly. Furthermore, the model correctly identifies the turn for disambiguation. However, for more complicated instances such as the third example, the model mixes up the reference mentions and identifies the wrong value for the attribute. We also provide examples of all subtasks results (MM-Disamb, MM-Coref, MM-DST, Response Generated Retrieval) with the corresponding VR scene in Figure 4, 5, 6, 7, and 8
